Experiment No. 4
Implement a program on method and constructor overloading.
Date of Performance:
Date of Submission:

**Aim:** Implement a program on method and constructor overloading.

**Objective:** To use concept of method overloading in a java program to create a class with same function name with different number of parameters.

**Theory:**

Method Overloading is a feature that allows a class to have more than one method having the same name, if their argument lists are different. It is similar to constructor overloading in Java, that allows a class to have more than one constructor having different argument lists.

Example: This example to show how method overloading is done by having different number of parameters for the same method name.

Class DisplayOverloading

```
{  
    public void disp(char c)  
    {  
        System.out.println(c);  
    }  
    public void disp(char c, int num)  
    {  
        System.out.println(c + " "+num);  
    }  
}
```

Class Sample

```
{
```

# Vidyavardhini's College of Engineering and Technology

## Department of Artificial Intelligence & Data Science

```
Public static void main(String args[])
{
    DisplayOverloading obj = new DisplayOverloading();
    Obj.disp('a');
    Obj.disp('a',10);
}
}
```

Output:

A

A 10

Java supports Constructor Overloading in addition to overloading methods. In Java, overloaded constructor is called based on the parameters specified when a new is executed.

Sometimes there is a need of initializing an object in different ways. This can be done using constructor overloading.

For example, the Thread class has 8 types of constructors. If we do not want to specify anything about a thread then we can simply use the default constructor of the Thread class, however, if we need to specify the thread name, then we may call the parameterized constructor of the Thread class with a String args like this:

```
Thread t= new Thread (" MyThread ");
```

**Code:**

```
class Box {
    double width, height, depth;
    Box(double w, double h, double d)
    {
        width = w;
        height = h;
        depth = d;
    }
}
```

# Vidyavardhini's College of Engineering and Technology

## Department of Artificial Intelligence & Data Science

```
Box() {
    width = height = depth = 0;
}
Box(double len) {
    width = height = depth = len;
}
double volume() {
    return width * height * depth;
}
}
public class Test {
    public static void main(String args[])
    {
        Box mybox1 = new Box(80, 90, 100);
        Box mybox2 = new Box();
        Box mycube = new Box(7);
        double vol;
        vol = mybox1.volume();
        System.out.println("Volume of mybox1 is " + vol);
        vol = mybox2.volume();
        System.out.println("Volume of mybox2 is " + vol);
        vol = mycube.volume();
        System.out.println("Volume of mycube is " + vol);
    }
}
```

### Output:-

Volume of mybox1 is 720000.0

Volume of mybox2 is 0.0

Volume of mycube is 343.0

```
C:\Users\admin\Desktop\JL>java Test.java
Volume of mybox1 is 720000.0
Volume of mybox2 is 0.0
Volume of mycube is 343.0
```

### Conclusion:

Comment on how function and constructor overloading used using java

→

#### 1. Function (Method) Overloading

- Definition: Multiple methods with the same name but different parameter lists within the same class.
- Purpose: Allows methods to perform similar tasks with varying argument types or numbers.
- Example:

- `int add(int a, int b)`

#### 2. Constructor Overloading

- Definition: Multiple constructors with different parameter lists within the same class.
- Purpose: Provides different ways to initialize an object based on provided arguments.
- Example:

- `Book()`

- `Book(String title, String author)`

- `Book(String title, String author, int year)`
